kNN Predictive Models

kNN is discriminative, non-parametric predictive model

• For kNN classifier, the mathematical formulation is

$$\hat{h}(\boldsymbol{x}) = \underset{j \in \{1, \dots, K\}}{\operatorname{argmax}} \frac{1}{k} \sum_{\boldsymbol{x}_i \in N(\boldsymbol{x})} I(y_i = j)$$

• For kNN regressor, the mathematical formulation is

$$\hat{h}(\boldsymbol{x}) = \frac{1}{k} \sum_{(\boldsymbol{x}'', \boldsymbol{y}'') \in N(\boldsymbol{x})} \boldsymbol{y}''.$$

One popular choice of distance in kNN is the Minkowski distance of order/degree r:

$$d(\boldsymbol{x}, \boldsymbol{z}) = \|\boldsymbol{x} - \boldsymbol{z}\|_r = \left(\sum_{i=1}^p |x_i - z_i|^r\right)^{\frac{1}{r}}, \quad \boldsymbol{x}, \ \boldsymbol{z} \in \mathbb{R}^p.$$
 (2.1)

Note that $\|\cdot\|^r$ is called the ℓ^r norm.

When r = 1, we have the Manhattan distance:

$$\|\boldsymbol{x} - \boldsymbol{z}\|_1 = |x_1 - z_1| + |x_2 - z_2| + \dots + |x_p - z_p|.$$

When r = 2, we have the Euclidean distance:

$$\|\boldsymbol{x} - \boldsymbol{z}\|_2 = \sqrt{(x_1 - z_1)^2 + (x_2 - z_2)^2 + \dots + (x_p - z_p)^2}.$$

There are other distance / dissimilarity functions which are used in specific cases:

- Gower; Tanimoto; Jaccard; Mahalanobis
- 1. The given table provides a training data set containing six observations, three predictors and one qualitative response variable. Suppose we wish to use this data set to make a prediction for Y when $X_1 = X_2 = X_3 = 0$ using k-nearest neighbours.

Obs.	X_1	X_2	X_3	Y
1	0	3	0	Red
2	2	0	0	Red
3	0	1	3	Red
4	0	1	2	Green
5	-1	0	1	Green
6	1	1	1	Red

(a) Compute the Euclidean distance between each observation and the test point (TP).

	Obs.	X_1	X_2	X_3	Y	Distance
	1	0	3	0	Red	3
	2	2	0	0	Red	2
Solution.	3	0	1	3	Red	$\sqrt{10} \approx 3.1623$
	4	0	1	2	Green	$\sqrt{5} \approx 2.2361$
	5	-1	0	1	Green	$\sqrt{2} \approx 1.4142$
	6	1	1	1	Red	$\sqrt{3} \approx 1.7321$

(b) What is our prediction with k = 1? Why?

Solution. Green. Observation 5 is the closest neighbour for k = 1.

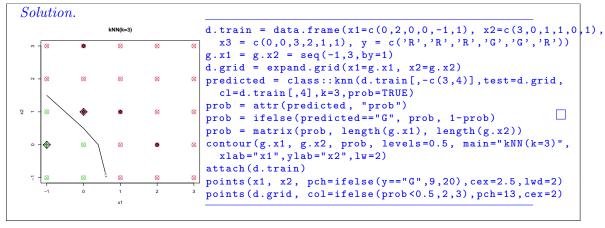

(c) What is our prediction with k = 3? Why?

Solution. Red. Observations 2, 5 and 6 are the closest neighbours for k=3, which Y equal to (Red, Green, Red). The probability of Red is two-third, which is larger than 0.5. $\mathbb{P}(Y=\mathrm{Red})=\frac{2}{3}\geq 0.5$ Hence, the test point will be predicted to be Red.

(d) If the Bayes decision boundary in this problem is highly non-linear, then would we expect the optimum value for k to be large or small? Why?

Solution. Small. A small k would be flexible for a non-linear decision boundary, whereas a large k would try to fit a more linear boundary because it takes more points into consideration.

(e) By considering X_1 and X_2 only, sketch the 3-nearest neighbours decision boundary for range $-1 \le X_1 \le 3$ and $-1 \le X_2 \le 3$, with the distance measure used in (a). Assume that X_1 and X_2 can only take integer values.

2. (Final Exam May 2023 Sem, Q5(a)(i)) Given the training data with features X_1 , X_2 and the label Y in Table 5.1.

Obs.	Petal.Length	Petal.Width	Sepal.Length	Species
1	1.5	0.2	5.0	setosa
2	1.1	0.1	4.3	setosa
3	4.0	1.2	5.8	versicolor
4	3.3	1.0	4.9	versicolor
5	5.4	2.1	6.9	virginica
6	5.1	1.9	5.8	virginica

Table 5.1: Training data with features Petal.Length, Petal.Width, Sepal.Length and the label Species of iris flower.

Given an iris flower with a petal length of 3.9, a petal width of 1.4 and a sepal length of 5.2. Use the Euclidean distance and the supervised learning model kNN (k=3) to predict the Species of the iris flower. (7 marks)

Solution. By calculating the Euclidean distance from the point (3.9, 1.4, 5.2) to the points in the training data, we can obtain the following table:

Petal.Length	Petal.Width	Sepal.Length	Species	Distance
1.5	0.2	5.0	setosa	2.6907
1.1	0.1	4.3	setosa	3.2156
4.0	1.2	5.8	versicolor	0.6403
3.3	1.0	4.9	versicolor	0.7810
5.4	2.1	6.9	virginica	2.3728
5.1	1.9	5.8	virginica	1.4318

.....[6 marks]

3. (Final Exam May 2024 Sem, Q5(a)) Given the training data with four numeric features "bill length" (unit: mm), "bill depth" (unit: mm), "flipper length" (unit: mm), "body mass" (unit: g) and the label "species" in Table 5.1.

Table 5.1: Training data of the penguin data with three types of penguins — Adelie, Chinstrap and Gentoo.

Obs.	bill length	bill depth	flipper length	body mass	species
A	41.1	19.1	188	4100	Adelie
В	50.6	19.4	193	3800	Chinstrap
\mathbf{C}	45.7	17.0	195	3650	Chinstrap
D	43.4	14.4	218	4600	Gentoo
\mathbf{E}	44.5	14.7	214	4850	Gentoo
\mathbf{F}	35.9	19.2	189	3800	Adelie
G	36.0	17.9	190	3450	Adelie
Η	50.0	15.2	218	5700	Gentoo

(i) Use the supervised learning model kNN (k=3) with the Euclidean distance to predict the species of a penguin with a bill length of 38.9 mm, a bill depth of 17.8 mm, a flipper length of 181 mm and a body mass of 3625 g. You may round the distance to 2 decimal places.

(9 marks)

Solution. By calculating the Euclidean distance from the point (46.5, 14.8, 217, 5200) to the points in the training data, we can obtain the following table:

Obs.	bill length	bill depth	flipper length	body mass	species	Dist
A	41.1	19.1	188	4100	Adelie	475.0584
В	50.6	19.4	193	3800	Chinstrap	175.8080
\mathbf{C}	45.7	17.0	195	3650	Chinstrap	29.4598
D	43.4	14.4	218	4600	Gentoo	975.7181
\mathbf{E}	44.5	14.7	214	4850	Gentoo	1225.4611
\mathbf{F}	35.9	19.2	189	3800	Adelie	175.2140
\mathbf{G}	36.0	17.9	190	3450	Adelie	175.2553
H	50.0	15.2	218	5700	Gentoo	2075.3612

The 3 nearest neighbours are observations C, F and G, which correspond to species Chinstrap, Adelie and Adelie. Therefore, the prediction of the species of the penguin

	is Adelie
(ii)	Based on your calculation in part (i), explain the problem with predictive modelling and what data preparation step is required to resolve the problem. (2 marks) Solution. Problem: the data are not scaled — "body mass" has a large variation compare to other features
More F	Performance Evaluation
`	2022 Final Q1(d)) Explain the steps in (i) validation set approach and (ii) k -fold cross ation and state each advantages and disadvantages. (5 marks)
val val fit mo Th fea Th	lution. (i) Validation set approach shuffles the data and splits it into training set and lidation/test set. The training dataset is the sample of data used to fit the model; the lidation dataset is the sample of data used to provide an unbiased evaluation of a model on the training dataset while tuning model hyperparameters. The evaluation becomes be biased as skew on the validation dataset is incorporated into the model configuration. The evaluation dataset may also play a role in other forms of model preparation, such as a sturre selection
(ii) set	mpling
tic	lvantage: This approach is less prone to biasness problem and less dependent on a parular sampling. It is used to tune model hyperparameters instead of a separate validation taset
	sadvantage: When the data size is large and the k is large, the scoring process can be ry time consuming $[0.5 \text{ mark}]$
5. Wha	t are the advantages of k -fold cross validation relative to
(a) V	Validation set approach
	Solution. The estimate of the test error rate can be highly variable depending on which observations are included in the training and validation sets. Secondly, the validation set error rate may tend to overestimate the test error rate for the model fit on the entire data set, which is the overfitting problem.
(b) I	Leave-one-out cross validation (LOOCV) Solution. LOOCV is a special case of k -fold cross-validation with $k = n$. Thus, LOOCV is the most computationally intense method since the model must be fit n times. In addition, LOOCV has higher variance , but lower bias , than k -fold cross validation.

- 6. (May 2019 Final Q3)
 - (a) Supervised learning includes classification and regression.
 - (i) State the difference between classification and regression in term of response variable.
